Linked lists - One-way lists

- A **linked list** is a data structure in which the objects are arranged in a linear order. Unlike an array, however, in which the linear order is determined by the array indices, the order in a linked list is determined by a pointer in each object. *Source: Introduction to Algorithms by Cormen et. al.*
- Types:
 - Simple one-way list (S1L)
 - One-way lists with header node (H1L)
 - Cyclic one-way list (C1L)
 - Simple two-way or doubly linked list (S2L)
 - Cyclic two-way list (C2L) with header

Simple one-way list (S1L)

$L_1 = \odot$

- Each list element has its general data, and a pointer pointing to the next element in the list. If it's the last element, the pointer is NULL.
- L points to the first element, but L is NOT an element in itself, nor is it a type of E1.

E1
$+key : \mathcal{T}$
$\dots$ // satellite data may come here
$+next : \mathbf{E1}^*$
$+\mathbf{E1}() \{ next := \odot \}$

Simple one-way list (S1L) - Iterating and Searching

S1L_search(L:E1*, k:T) : E1*

S1L_search(L:E1*, k:T) : E1*

• Iterating:

- p: pointer to one of the elements p: E1*
- p→key: the value of the list element.
- p→next: pointer value of the next element (if any).
- Allocating a new element: p:= new E1
- Deleting list element: delete p
After deletion, referencing any fields is invalid.

• Searching:

- Let L point to an ordered list of S1L. Find an element in L with key 'k'. If one such element exists, return with its pointer, otherwise return null.

Simple one-way list (S1L) - Insertion

• Insertion:

- Let L point to an ordered S1L. Insert a key into the list, and keep it ordered.
- If such key already exists, do nothing. (set)
- The position of the key can be in the four possible places:
- The element should be somewhere in the middle,
- The element is the largest, making it the last,
- The element is the smallest, making it the first,
- The list is empty.

Simple one-way list (S1L) - Insertion

- At the end:
 - Inserting to the end of the list:
 - p is null since every element is smaller than the key to be inserted.
 - pe then is the last element, allowing us to insert after it.
- At the start:
 - Inserting at the beginning means that L should now point to the new element (pe is null):
 - Inserting into an empty list means that both p , and pe are null:

Simple one-way list (S1L) - Insertion

S1L_insert(&L: E1*, k: T)

Simple one-way list (S1L) - Deletion

- Deletion:

- Once again, L points to a sorted S1L. Delete an element if it exists.
- If the deletion is successful (exists) return true, otherwise false.
- To delete the element and keep the list intact, we need the previous element once again.
- In case of (successful) deletion, the following cases are possible:
 - Deleting the first element.
 - Deleting an inner element,
 - Deleting the last element.

Simple one-way list (S1L) - Deletion

S1L_delete(&L:E1*, k:T):B

One-way lists with header node

One-way lists with header node (H1L)

- Header element:
 - As we've seen these algorithms need to handle the beginning of the list differently from the other cases since *pe* is null.
 - To solve this issue, and avoid unnecessary branches we introduce a header element.
 - This way the list will always have an E1 element, sort of a placeholder!
 - This also means that we however don't store data in it.

- Searching will be slightly different:
 - We start from the first element after the head

One-way lists with header node (H1L) - Insertion

One-way lists with header node (H1L) - Insertion

- Differences:
 - L is not passed by reference.
 - Start: pe is the header, p is the first element (can be null)
 - No branch is needed since pe is never null.

One-way lists with header node (H1L) - Deletion

One-way lists with header node (H1L) - Deletion

S1L_delete(&L:E1*, k: T):B

H1L_delete(L: E1*, key: T) : B

- Differences:

- L is not passed by reference.
- Start: pe is the header, p is the first element (can be null)
- No branch is needed since pe is never null.

Illustration prob. for One-way l

Reversing an S1L list

- Let L point to an S1L. Reverse the order of elements.
- Input:
 - $L \rightarrow \text{one} \rightarrow \text{two} \rightarrow \text{three} \rightarrow \text{four}$
- Output:
 - $L \rightarrow \text{four} \rightarrow \text{three} \rightarrow \text{two} \rightarrow \text{one}$
- Idea:
 - 'Deconstruct' the original list, and p points to the first element.
 - Set L to empty list //L:=0
 - Iterating on the original list, and inserting each element right at the beginning of L will result in the reversed list.

Reversing an S1L list

ReverseList(&L:E1*)

- q is the element to be inserted at the new beginning
- We must step to the next element in the previous list, otherwise, we'd lose track of the original list
- Inserting q: the previous first element should come after q, and q should be the new first element.

Sieve of Eratosthenes with S1L

- Using Eratosthenes' algorithm, create a list of prime numbers smaller than n .
- Idea:
 - Create a list of integers smaller than n . 1 is not a prime, delete. 2 is the first prime, and from now on we have to delete every second element (since they are a multiple of 2, and therefore not primes.)
 - From the remaining elements, the next is 3, it's a prime, keep it, and delete the multiples of 3 once again.
 - And so on until we reach the last element. The remaining elements are all primes.

Sieve of Eratosthenes with S1L

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
--------------	---	---	--------------	---	--------------	---	--------------	--------------	---------------	----	---------------	----	---------------	---------------	---------------	----	---------------	----	---------------

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
--------------	---	---	--------------	---	--------------	---	--------------	--------------	---------------	----	---------------	----	---------------	---------------	---------------	----	---------------	----	---------------

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
--------------	---	---	--------------	---	--------------	---	--------------	--------------	---------------	----	---------------	----	---------------	---------------	---------------	----	---------------	----	---------------

Sieve of Eratosthenes with S1L

PrimeSieve(n:N):E1*

p points to next prime.

q will point to the follow-up elements, and we check if the given element is a multiple of p or not. If yes, delete.

Given that we deleted the multiples of p (and the multiples before it), the next element after p will also go to be a prime.

Generate(n:N):E1*
